It was subsequently adapted by [Malika Ihle](#) during her time at Reproducible Research Oxford. This current work by Sarah von Grebmer zu Wolfsturn, Peter Edelsbrunner and Malika Ihle is licensed under a CC-BY 4.0 [Creative Commons Attribution 4.0 International License](#). This licence permits unrestricted re-use, distribution, and reproduction in any medium, provided the original work is properly cited.

Speaker Notes: The Creative Commons Attribution 4.0 International (CC BY 4.0) license permits you to freely use, share, and adapt the licensed material for any purpose, including commercial use. This means you can copy, redistribute, remix, transform, and build upon the work without asking for permission.

However, there are some important conditions you must follow. You are required to give appropriate credit to the original creator, provide a link to the license, and indicate if you made any changes to the material. Additionally, you cannot apply any legal terms or technological measures that would restrict others from using the work under the same freedoms.

Instructor Notes: You are free to edit, modify and add/delete slides to tailor the content to your learners. However, make sure to give appropriate credit to the original creators of this content as described in the licence agreement.

Contribution statement

Creator: Von Grebmer zu Wolfsturn, Sarah ( [0000-0002-6413-3895](#))

Reviewer: Ihle, Malika ( 0000-0002-3242-5981)

Consultant: Edelsbrunner, Peter ( 0000-0001-9102-1090)

Speaker Notes: These are the **speaker notes**. You will see a script for the presenter for every slide. In presentation mode, your audience will not be able to see these speaker notes, they are only visible to the presenter.

Instructor Notes: There are also **instructor notes**. For some slides, there will be pedagogical tips, suggestions for activities and troubleshooting tips for issues your audience might run into. You can find these notes underneath the speaker notes.

Accessibility Tips: Where applicable, this is a space to add any tips you may have to facilitate the accessibility of your slides and activities. An example for an accessibility tip could be: When demonstrating Git commands, speak aloud what you are typing. Do not rely solely on the terminal output or visual cues on the screen.

Prerequisites

Important

Before completing this submodule, please carefully read about the prerequisites.

Prerequisite	Description	Link/Where to find it
Laptop/PC with internet access	Admin rights for download/install	-
R and RStudio installed	Latest versions of both R and RStudio	https://posit.co/download/rstudio-desktop/
Basic R skills	3.2 Introduction to R - Part I	LINK
Advanced R skills	3.3 Introduction to R - Part II	LINK
GitHub account	Free account for GitHub	Join at https://github.com/join

Speaker Notes: The basic requirements to follow these slides are a laptop or desktop with admin rights to download and install software, and the latest installations of R and RStudio. Basic knowledge on R and RStudio, ideally as demonstrated through the completion of the two previous submodules R Part I and Part II is also a prerequisite. Specifically, learners are expected to have an intermediate familiarity with R, for example with data wrangling,

reshaping, subsetting, plotting and creating basic R functions. Finally, for this submodule, learners will need their own GitHub account, which is free to create on github.com.

Instructor Notes: Before you get started on this submodule with your audience, you need to ensure that the audience fulfills these criteria. **Additional important tip:** If you are planning to deliver these slides synchronously in class, here is a proposed lesson plan (90 minutes + homework assignment):

- 3 minutes to situate this new class within the overall course, clarify questions from the previous class etc.
 - 5 minutes for the WHY of version control
 - Use of interactive tools and group discussions to work out what challenges learners face and to get the curious about version control as a potential solution
 - 5 minutes for pre-content survey + survey discussion to explore how familiar learners are already with version control
 - 5 minutes introduction to Git and GitHub, exploration of the Git - GitHub workflow
 - Remaining class (approx 60 minutes left): **Setting up Git** (= slides until the break)
 - 5 minutes before the end: Final survey (currently pre-break survey) to check where people are at
 - 2 minutes before the end: Homework assignment discussion - **RStudio Project and Git** (aka all content after the break in the slides as they are now): 1. Creating an RStudio Project 2. Setting up practice project 3. Getting your project under version control 4. Making changes to your project 5. Committing changes 6. Connecting the local repository to GitHub
-

Questions from the previous submodule

Any remaining questions about the most recent content and/or practical exercises?

Speaker Notes: Are there any questions that were left unanswered from the previous session?

Instructor Notes: - **Aim:** This slide is dedicated to clarifying questions from the previous submodule and/or to discuss assignments. You may need to add slides depending on the homework assignment and if you could already foresee difficulties. This reflection moment is critical for the learning process to ensure that learners are on the same page and have been able to achieve the learning goals of the previous workshop.

Where are we at?

Previously:

- Familiarization with the basics of R
- More advanced R skills: data manipulation, reshaping, functions, plotting
- Using R for your own scientific work

Up next:

- Facing challenges in our workflow and how to solve them
- Enhancing reproducibility and our own accountability
- Facilitating collaboration

Speaker Notes: In the previous two sessions, we have familiarized ourselves with R and RStudio. We have learned what we can use R for and we tested some features of R in RStudio, such as data manipulation, reshaping, functions, plotting etc. Next, what we want to use this session is once again use these skills within RStudio, but with a stronger focus on enhancing the reproducibility of our work. We also want to increase our own responsibility for the steps we are taking within the research process. We will start to learn about tools that can help us to facilitate collaboration across different parties and maybe even disciplines, and we will put a special focus on being transparent in every step so that our methods and decision making process is clear to others that come across our work.

Instructor Notes:

- **Aim:** Place the topic of the current submodule within a broader context.
 - Remind learners what you are working towards and what the bigger picture is.
-

Learning goals

- **Understand** the problem(s) that can be solved by version control
- **Install and configure** Git
- **Set up** the connection between your computer and GitHub
- **Create** an RStudio Project under version control for a reproducible workflow
- **Make** changes within RStudio and **commit** changes locally
- **Connect** local and remote repositories for your work

Speaker Notes: In this session, we will focus on the following elements. Do not worry if these terms sound unfamiliar to you at this point, we will go through each step one by one.

- **Understand** the problem(s) that can be solved by version control
- **Install and configure** Git

- **Set up** the connection between your computer and GitHub
- **Create** an RStudio Project under version control for a reproducible workflow
- **Make** changes within RStudio and **commit** changes locally
- **Connect** local and remote repositories for your work

Instructor Notes:

- **Aim:** Formulate specific, action-oriented goals learning goals which are measurable and observable in line with Bloom's taxonomy (Anderson et al., 2001; Bloom et al., 1956)

Accessibility Tips:

- Place an emphasis on the **verbs** of the learning goals and choose verbs that align with the skills you want to develop or assess.
-

Key terms and definitions

- **Reproducible workflows:**
- **RStudio Project:**
- **Git:**
- **GitHub:**
- **Repositories:**

Speaker Notes: These will be some key terms we will explore more today. Do not worry if some of them do not sound familiar to you yet. I want you to first write down in the next two minutes for yourselves what each of these concepts means to you. Then, take 3 minutes to discuss with your neighbour what you have collected. Finally, let us discuss as a group. There are no right or wrong answers.

Instructor Notes: Base yourself on conceptual change theory and examine existing concepts in relation to some key terms. Use the think-pair-share paradigm: **1) THINK:** learners first write down for themselves what they understand by these concepts. **2) PAIR:** form pairs among your learners and have them discuss their current understanding of these concepts. **3) SHARE:** Ask for volunteer pairs to share their conclusions and thought process. Compare the descriptions provided by the learners: Are there any visible divergences or central aspects that they did not mention or mentioned differently? Re-examine the formation of new concepts at the end of the lesson.

Accessibility Tip: Note that this slide only works for a synchronous in-class setting. Skip if appropriate.

Key terms and definitions

- **Reproducible workflows:** Structured process ensuring that the methods can be consistently repeated by others using the same approach, data and tools
- **RStudio Project:** A way to store all files related to one R project in one place (R scripts, files, workspace, history ..) via a so-called .Rproj file
- **Git:** Version control system that tracks and manages changes to files and code
- **GitHub:** Cloud-based version control platform for hosting Git repositories which includes collaboration features
- **Repositories:** Git terminology for a folder where the contents of the folder are being tracked by Git

Speaker Notes:

- **Reproducible Workflows:** A reproducible workflow refers to a structured process that ensures methods can be consistently repeated by others. This means that anyone who follows the same steps, using the same data and tools, should be able to achieve the same results. Reproducibility is essential in science and research because it helps verify findings, promotes transparency, and allows others to build on your work. By creating workflows that are transparent, well-documented, and accessible, you ensure that your research is both credible and trustworthy.
- **RStudio Project:** An RStudio Project is a convenient way to organize all the files related to a specific R project in one centralized location. This includes not only your R scripts but also any data, workspace settings, history, and outputs. By creating a project in RStudio and a corresponding .Rproj, you make it easier to maintain a consistent working environment, ensuring that everything you need is in one place. This organization is especially useful when sharing projects with collaborators or when you need to continue working on a project at a later time, as it simplifies managing dependencies and avoids issues related to missing files or incorrect paths.
- **Git:** Git is a popular version control system that helps you track and manage changes to your files and code. With Git, you can create commits, which are snapshots of your project at specific points in time. This makes it easy to monitor your progress, and roll back changes if needed. Git also supports branching, allowing you to work on new features or experiments without affecting the main project. Git's decentralized nature means that each contributor has a full copy of the project's history, ensuring robust tracking and flexibility.
- **GitHub:** GitHub is a cloud-based platform built on top of Git that facilitates version control and collaboration. It hosts Git repositories online, making it easy to share your code with others, contribute to open-source projects, and track issues or bugs. GitHub offers additional features like pull requests, which allow collaborators to propose changes to a project and review those changes before they are merged into the main codebase. It also provides tools for project management, documentation, and continuous integration, making it an essential tool for modern software development and collaboration.

- **Repositories:** Git terminology for a folder whose content is tracked by Git
-

Some realistic challenges in our (study and work)lives ...

Challenge 1: Document and project management

Multiple versions of the same project/document “floating” around on your PC.

i Sound familiar?

What is your current **document naming and management** strategy?

Speaker Notes: So here we see our typical student — they've got 100 versions of the same file on their laptop. This might look funny, but we have all been there, whether it's a paper draft, a dataset, or an analysis script. File and data management is hard, and we have to somehow juggle multiple versions of files, so it is easy to lose track of which version is the “right” one.

Instructor Notes: Adjust the example to tailor it to the main file type of your audience. Perhaps even show your own data organisation system from a project from many years ago to make learners relate more. Ask for volunteers to describe their current document management strategies.

Challenge 2: When hardware fails

Laptop dies, files are accidentally deleted.

i Note

Mentally raise your hand if this happened to you before.

Speaker Notes: Here is once again our student, who is the victim of one of the most common threats to good science: hardware failure. It could be a coffee spill, a dropped laptop, a lost USB drive, or a hard disk crash, all different flavors of the same disaster and very realistic scenarios in student and researcher life.

Instructor Notes: Describe an example from your own research or student career and describe the impact it had at the time. This is another reason why version control systems like Git, especially when used with remote hosting services such as GitHub, are so powerful. They do not just track your changes; they back up your work in multiple locations, so even if your laptop meets an unfortunate end, your work does not.

Challenge 3: “What on earth did I do again..?”

Projects evolve, it is easy to **forget** what we last changed or did on the project.

Speaker Notes: This might yet be another problem that could be familiar to some of you: You have a new assignment and it reminds you of an old assignment. You decide to copy that folder over but are now wondering what the last thing you did was and how you solved the assignment last time. Sometimes it takes months or years until you come back to your old project, and it is almost impossible to remember why we made certain changes, what data we used, or how the results were produced, especially if all we have are scattered files in random folder with no context.

Instructor Notes: Additional speaker notes for clarity: We've all opened an old project and thought, “What was I even doing here?” Without clear records, it's impossible to remember how results were produced or why changes were made. This is where Git comes in, because changes are tracked and years later, you see exactly what you did and why.

Challenge 4: “But I just wanted to try to ...”

Especially with coding, trying new ideas can **break** your code.

Speaker Notes: This is another situation that some of you may recognise: we are working on some code, we make a “small” change to try something new or to add a small new feature and suddenly nothing works anymore.

Instructor Notes: Without version control, it is hard to get back to a working state or see what went wrong. Git makes this safe: you can experiment on a branch, and if it fails, simply return to the last working version.

Who is familiar with these problems?

- a. Inconsistent data and file management aka **I cannot find my files**
- b. Hardware failures (coffee spill, laptop dropped, lost laptop, broken USB) aka **my work is lost**
- c. Extended periods of time between project actions aka **I forgot what I was working on**
- d. Experimentation with new features aka **I tried something and my laptop is now smoking**
- e. All of the above
- f. None of the above (are you *sure*?)

Speaker Notes: Your turn: Scan the QR code and we can have a look who of you is familiar with one or more of these issues.

Instructor Notes: Select the problem survey when prompted. Closely examine the answers given and create a shared understanding that many students in class are experiencing similar issues.

Accessibility Tip: Note that this slide only works for a synchronous in-class setting. Skip this slide as appropriate.

A realistic solution to these challenges?

Version control

“Version ... what?”

- **Version control** = system that **records changes** to files **over time** by recording the difference between two files
- **Tracks modifications** and edits
- Helps you **manage different versions**
- Allows you to **recover previous versions**

Speaker Notes: Version control is a system that records changes made to files over time. Specifically, it saves the **difference** between two files. It enables you to track the history of modifications, making it easy to see who changed what, when, and why. This is particularly valuable when working on code or large projects with many files, as it helps you manage different versions, and recover previous versions if something goes wrong. With version control, you can safely experiment with new changes without fear of losing important work, as you can always revert to a stable version of the project.

Instructor Notes: Take your time with this section as it explains the WHY of version control. Learners should recognize their own challenges and be curious about how exactly one could overcome these challenges. More importantly, they should get a first idea how version control could be a tool to overcome their *own* challenges and that therefore it could be beneficial for *them personally*.

Before we start: Survey time!

Figure 1: Select the starting survey option!

Speaker Notes: First, I would like to find out more about how familiar you are with different concepts we will touch upon later. Please scan the QR code and select the starting survey when prompted.

Instructor Notes:

- **Aim:** The pre-submodule survey serves to examine learners' prior knowledge about version control and related concepts. Note that this survey cannot be completed in an

asynchronous setting because the survey results cannot be displayed.

Accessibility Tip: Note that this slide only works for a synchronous in-class setting. Skip this slide as appropriate.

What is your level of familiarity with version control?

- a. I have never heard of it before.
 - b. I have heard of it but have never worked with it.
 - c. I have a basic understanding and some experience with it.
 - d. I am very familiar and have worked with it extensively.
-

Which of the following concepts or skills do you currently feel most confident about in relation to version control? (Select all that apply)

- a. Git
 - b. GitHub
 - c. Repositories
 - d. RStudio Project
 - e. I am not sure about any of these concepts.
-

**On a scale of 1 to 5, how comfortable are you with using Git for version control?
(1 = Not comfortable at all, 5 = Very comfortable)**

- a. 1
 - b. 2
 - c. 3
 - d. 4
 - e. 5
-

Discussion of survey results

What do we see in the results?

Speaker Notes: Let us have a look at these results.

Instructor Notes:

- **Aim:** Briefly examine the answers given to each question interactively with the group. Use visuals from the survey to highlight specific answers. If *everyone* selects Git and GitHub in the question concerned with the familiarity with these concepts, keep your explanations and definitions short: “okay, you have heard about X, so I will only briefly revisit this”. If the majority of learners state that they are currently extremely uncomfortable with using Git, provide reassurance that they are in the right spot. If many people are extremely comfortable with all concepts, ask them if they would prefer going through the slides and tasks by themselves.

Accessibility Tip: Have people work in pairs if someone did not bring their phone/does not have a phone. This survey also cannot be completed in an asynchronous setting.

Git: What is it?

Git is a free and **open source software**. With Git, you can:

- **Track changes** to files across folders over time, seeing what was changed, when and by whom
- **Collaborate** efficiently within a team as multiple people can work on the same folders and files

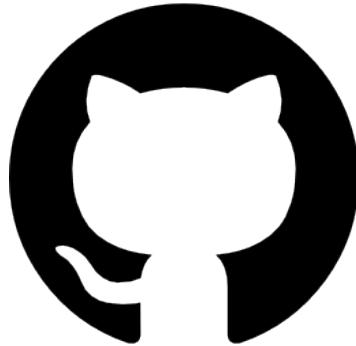

Speaker Notes: Diving into the solution to some of the challenges with discussed earlier, Git is a popular version control system that helps you track and manage changes to your files and code. With Git, you can create commits, which are snapshots of your project at specific points in time. This makes it easy to monitor your progress, roll back changes if needed, and collaborate effectively with others. Git also supports branching, allowing you to work on new features or experiments without affecting the main project. Git's decentralized nature means that each contributor has a full copy of the project's history, ensuring robust tracking and flexibility.

Instructor Notes: Examine the conceptual understanding of this term before proceeding.

GitHub: What is it?

GitHub is a **cloud-based version control platform** that uses Git to track changes and hosts Git repositories.

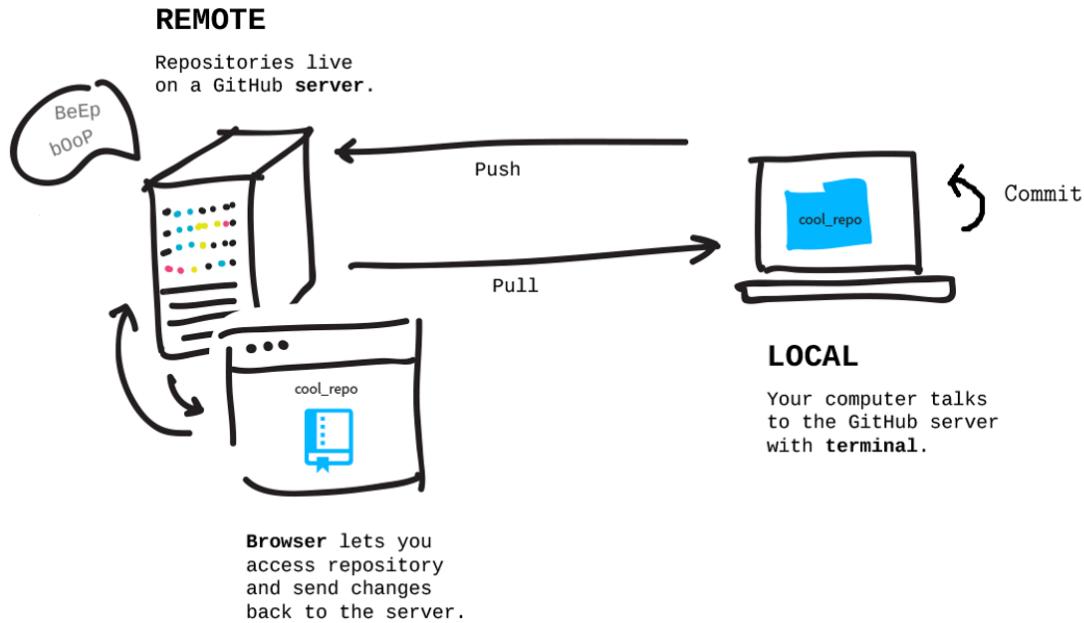

- Allows multiple people to **collaborate** on the same project
- Collaborators can **share** repositories, code etc. and ask for **feedback**, initiate discussions and point out bugs and issues
- GitHub **stores** all files remotely, making it accessible from anywhere

Speaker Notes: GitHub is a cloud-based platform built on top of Git that facilitates version control and collaboration. It hosts Git repositories online, making it easy to share your code with others, contribute to open-source projects, and track issues or bugs. GitHub offers additional features like pull requests, which allow collaborators to propose changes to a project and review those changes before they are merged into the main codebase. It also provides tools for project management, documentation, and continuous integration, making it an essential tool for modern software development and collaboration.

Instructor Notes: Examine the conceptual understanding of this term before proceeding.

The Git - GitHub workflow

Speaker Notes: Let's break down the basic steps of how Git and GitHub work together:

- **Local repository (aka your computer):** When you start working on a project, you create a local repository on your computer. This is simply a folder where all your project files are kept. Git helps you track changes to these files over time by taking snapshots of them every time you save or modify something important. For example, imagine you're writing code or working on a document. Each time you make significant changes, you can use Git to save a snapshot (called a commit) of your work. This allows you to keep track of your progress, go back to previous versions if needed, and see what changes have been made.
- **Remote repository (GitHub):** While your local repository is on your computer, GitHub is a platform on the internet that hosts your project remotely. Think of GitHub as a cloud-based storage for your project, where you can store the most up-to-date version of your work. Having a remote repository on GitHub is also helpful if you're collaborating with others. Instead of sending files back and forth, everyone can work on the same project from their own computers and update GitHub with their changes.
- **Pushing changes to GitHub:** Once you have made changes to your files and are happy with them, you can push those changes to the remote repository on GitHub. To "push" means to send your local changes to GitHub, making them available to anyone else who is working on the project. Think of pushing like uploading your updated work to the cloud.

- **Pulling changes from GitHub:** If you are collaborating with others, or if someone else has made changes to the project, you will need to make sure your local project is up-to-date. To do this, you can pull the latest version from GitHub. Pulling means downloading the latest version of the project from GitHub to your computer. This ensures that you have all the recent changes made by others, and it helps avoid conflicts when multiple people are working on the same project at the same time.

Instructor Notes: Take your time when explaining this workflow. If this slide is still too difficult to grasp, here is an even simpler explanation:

- Starting a project: You create a new project on your computer and initialize a local repository to start tracking your changes with Git.
 - Making changes: You write code or update documents. Every time you reach an important milestone, you save those changes with Git by making a commit.
 - Pushing to GitHub: When you're ready to share your progress with others (or back it up), you push your changes to GitHub. Now, your work is safely stored online.
 - Pulling updates: If someone else is working on the project or you've been away for a while, you can pull the latest changes from GitHub to your computer. This keeps your local copy in sync with everyone else's work.
-

#explainlikeIamfive

In pairs, explain the Git - GitHub workflow to your partner. What is the difference between **pushing** and **pulling**?

Speaker Notes: In pairs, I would like for you to explain to each other, in simple terms, what the Git-GitHub “workflow” entails. What role does Git play locally versus GitHub remotely? How does pushing and pulling connect the two? And what is the difference between the two?

Instructor Notes: Use this as an informal assessment moment to gauge if the general concepts of pulling and pushing are clear. Ask for one or two volunteer pairs who would explain the workflow in their own words to the rest of the audience. Then, make a transition into the practical aspect of this class.

How to use Git: Let's get started!

Installing Git: Windows

To install Git on Windows:

- Download Git from <http://git-scm.com/downloads>
- Download and run .exe file
- Accept all the default settings and keep clicking **Next**

Speaker Notes: To install Git on Windows, first visit <http://git-scm.com/downloads> and download the latest version of Git. Once the download is complete, run the .exe installer file. During the installation process, simply accept all the default settings and continue clicking ‘Next’ until the installation is finished. There’s no need to make any changes to the default options unless you have specific preferences. This will set up Git on your Windows machine with minimal effort.

Instructor Notes: Work alongslide your learners from a new laptop that does not have Git installed yet and leave enough time for learners to follow along. Check in regularly to detect issues. Whenever technical issues need to be dealt with, ask around if anyone experienced may jump in so you do not have to solve everything yourself.

Installing Git: MacOS

To install Git on MacOS:

- Download Git from <http://git-scm.com/downloads>
- Select first option suggesting to install git through installing homebrew
- Paste the line of command provided in their instructions in your terminal
- Accept the prompts appearing the terminal

Speaker Notes: To install Git on macOS, begin by visiting <http://git-scm.com/downloads> and downloading the latest version of Git. On the download page, select the first option that suggests installing Git via Homebrew, which is a package manager for macOS.

Instructor Notes: Work alongslide your learners from a new laptop that does not have Git installed yet and leave enough time for learners to follow along. Check in regularly to detect issues.

Installing Git: Ubuntu

To install Git on Ubuntu:

- Paste the following line into your terminal:

```
sudo apt-get install git-core
```

Speaker Notes: To install Git on Ubuntu, open your terminal and paste the following command: sudo apt-get install git-core. This command will install Git using Ubuntu's package manager. You may be prompted to enter your password to authorize the installation. Once the process is complete, Git will be successfully installed on your system.

Instructor Notes: Leave enough time for learners to follow along. Check in regularly to detect issues.

Configuring Git

Step 1: By default, Git is used through the **command line** interface, but can be used through RStudio (later in this session).

- **Windows:** Open Git Bash (start menu > *Git Bash*)
- **MacOS:** Open the *Terminal app*
- **Linux:** Open your distribution's *terminal emulator*

Speaker Notes: Git can be configured through the command line interface. Later, we will be able to use Git through RStudio, which we will cover later in this session. To configure Git via the command line, follow these steps depending on your operating system:

- On Windows, open Git Bash by searching for it in the Start menu (just type “Git Bash” and select it).
- On macOS, open the Terminal app, which you can find in the Applications > Utilities folder or search for using Spotlight.
- On Linux, open your distribution's terminal emulator (for example, GNOME Terminal, Konsole, or another terminal application specific to your Linux distribution).

Once you've opened the terminal, you'll be ready to start configuring Git through the command line.

Instructor Notes: Make sure to leave enough time for learners to find the terminal corresponding to their operating system.

Configuring Git

Step 2: Next, enter the following commands with your email one after the other (hitting ENTER after each command):

```
git config --global user.email "you@youremail.com"  
git config --global user.name "Your Name"
```

Speaker Notes: We will continue configuring Git. In the command line, type the following commands, one after the other, and hit enter after each command. Make sure to replace the email in quotes with your own email, and the name in quotes with your own full name. Do not remove the quotes.

Instructor Notes: Upon successful execution, learners should see no output from these commands. Emphasize the importance of using their own email addresses and names in quotes. Also highlight that the commands need to be typed **EXACTLY** as is, as the command line is highly sensitive to spelling, capitalization, punctuation and empty spaces.

Securing the connection between your computer and GitHub

You need to identify yourself and your machine to GitHub before interacting with GitHub repositories.

- **SSH keys** are a common way to manifest your identification to GitHub

! Important

SSH keys come in pairs, a public key that gets shared with services like GitHub, and a private key that is stored only on your computer. If the keys match, you're granted access. Setting up the SSH key has to be executed once per GitHub account and for **each** computer you will use to connect to GitHub.

Speaker Notes: Before you can interact with GitHub repositories, GitHub needs to recognize you and your machine. This is important to ensure that only authorized users can access and make changes to repositories. One common way to authenticate yourself and your machine is by using SSH keys.

SSH keys work by pairing a public key with a private key. The public key is shared with GitHub and stored on their servers, while the private key stays securely on your computer. When you try to connect to GitHub, it checks if the public and private keys match. If they do, you're granted access.

Note that setting up SSH keys is something you only need to do **once** per GitHub account. However, you will need to set up separate keys for each computer you use to connect to GitHub. This ensures that every device you use has its own secure authentication.

Remember, once the SSH keys are set up, they streamline your workflow with GitHub, allowing you to securely push, pull, and interact with repositories without needing to repeatedly enter your credentials.

Instructor Notes: Depending on the technical experience of the audience, go into more or less details about SSH keys. Stress that you need SSH keys to secure the connection between a specific computer and a specific GitHub account.

Checking for existing SSH key pair

Step 1: Before generating a new SSH key pair, check for existing key in your .ssh directory.

- **Windows:** Open Git Bash (`Windows start menu > type Git Bash into search bar`)
- **MacOS:** Open Terminal App
- **Linux:** Open your distribution's (or any other) terminal emulator

Speaker Notes: Before creating a new SSH key pair, it is important to check if you already have one. If you already have an SSH key pair, there is no need to generate a new one. You can simply use the existing key, which can save you time and avoid disrupting any current connections you have set up. In this first step we will check for an existing SSH key on different operating systems:

- **For Windows:** Start by opening Git Bash. You can find it by searching for “Git Bash” in the Start menu. Once it’s open, navigate to the .ssh directory to see if a key already exists.
- **For macOS:** On a Mac, open the Terminal app. You can find it by searching for “Terminal” in Spotlight or by navigating to Applications > Utilities. From there, you can check the .ssh folder to look for any existing keys.
- **For Linux:** If you are using Linux, open any terminal emulator you prefer, whether it’s the default terminal for your distribution or a third-party app. Then, check the .ssh directory for any existing SSH keys.

Instructor Notes: Make sure to leave enough time for learners to follow the instructions based on their operating system.

Checking for existing SSH key pair

Step 2: Enter the following command to list the content of the ssh directory:

```
ls ~/ssh
```

Speaker Notes: The second step is to list the contents of the .ssh directory. This will allow you to see if any SSH keys are already present. To do this, open your terminal (or Git Bash on Windows) and enter the following command: ls ~/ssh. This command will display a list of files located in the .ssh directory. If you already have SSH keys, you will likely see files such as id_rsa (private key) and id_rsa.pub (public key), or similarly named files like id_ed25519 and id_ed25519.pub.

Instructor Notes: Ask your audience to review the outputs of this command and to compare it to the following slide.

Checking for existing SSH key pair

Step 3: If there are existing ssh keys, they are named one of the following:

```
id_rsa.pub  
id_ecdsa.pub  
id_ed25519.pub
```

! Important

If you already have an SSH key pair, you can skip the section on how to generate a new SSH key pair. If you don't have an existing public and private key pair (which is to be expected!), or if you receive an error that ~/ssh doesn't exist, that this file location doesn't exist, or that you can't access this folder, go ahead and generate a new SSH key pair.

Speaker Notes: If there were already an SSH key pair, the command line output would be one of the ones indicated on this slide. In that case, it means that you already have an SSH key pair. You can therefore skip the section on how to generate a new SSH key pair.

However, if you do not have an existing public and private key pair (which is to be expected!), or if you receive an error that ~/ssh does not exist, that this file location does not exist, or that you cannot access this folder, we will go ahead and generate a new SSH key pair as our next step.

Instructor Notes: If there is an existing SSH key pair, learners can skip the section on how to generate a new SSH key pair. If there is no existing public and private key pair (which is

to be expected!), or if there is an error message saying that `~/.ssh` doesn't exist, that this file location doesn't exist, or that the folder cannot be accessed, learners can proceed with the generation of a new SSH key pair.

Generating a new SSH key pair

Step 1: In the command line, type the following (replacing the email here with your *own* email) to create a new SSH key pair with your email as a label:

```
ssh-keygen -t ed25519 -C "your_email@email.com"
```

Tip

Pay close attention to spacing and capital letters while typing.

Speaker Notes: As the first step to creating a new SSH key pair, type the following into the command line, replacing the email here with your *own* email to create a new SSH key pair with your email as a label: `ssh-keygen -t ed25519 -C "your_email@email.com"`. Pay close attention to spelling!

Instructor Notes: Learners need to pay close attention to spacing and capital letters while typing.

Generating a new SSH key pair

Step 2: When prompted to *Enter a file in which to save key*, press ENTER to accept the default file location. That should give you this prompt:

```
Generating public/private ed25519 key pair.  
Enter file in which to save the key (/Users/username/.ssh/id_ed25519):
```

Speaker Notes: In the next step, When prompted to *Enter a file in which to save key*, press ENTER to accept the default file location. That should give you this prompt you see in these slides: Generating public/private ed25519 key pair.

Enter file in which to save the key (/Users/username/.ssh/id_ed25519):

Instructor Notes: Remind your audience to check the output of the command.

Generating a new SSH key pair

Step 3: Next, you are asked to provide a passphrase in the terminal. Protecting your keys with a password is optional but highly recommended. Press ENTER after confirming your password.

```
Enter passphrase (empty for no passphrase):  
Enter same passphrase again:
```

⚠ Warning

When you type passwords in the command line, **nothing** is displayed, you are however still typing in the background. This is **normal behaviour** by the command line and *nothing* to be concerned about.

Speaker Notes: Next, you are asked to provide a passphrase in the terminal. Protecting your keys with a password is optional but highly recommended. Start typing the password next to the first prompt. Note that your input will be **invisible** and you will feel like you are not typing. This is **normal** behaviour. Just enter your password regardless. Re-confirm the password at the second prompt and press ENTER.

Instructor Notes: Emphasize the normal behaviour of the terminal that your audience is unable to see anything they type and that there is no need for concern.

Generating a new SSH key pair

Step 4: When the key generation is complete, you should see the confirmation below.

```
Your identification has been saved in /Users/username/.ssh/id_ed25519.  
Your public key has been saved in /Users/username/.ssh/id_ed25519.pub.  
The key fingerprint is:  
SHA256:6nr/zo0g7Bz7WMRwy34maBhQy1UZyX47gT+egRdlIhs your_email@email.com  
The key's randomart image is:  
+--[ED25519 256]---  
| .o++ |  
| o oF . o |  
| . o+ =.+. |  
| . + += . |  
| . +S++ |  
| . .oB= |  
| . +**=. |  
| o.==* o |
```

```
| .o.o*** . |  
+---[SHA256]---+
```

Speaker Notes: When the key generation is complete, you should see the confirmation below. This indicates that you have successfully generated your new public SSH key pair.

Instructor Notes: Encourage your learners to compare their output with the output on the slides.

Generating a new SSH key pair

Note

Done! You have successfully **generated your public SSH key pair**.

Speaker Notes: Congratulations! You have successfully **generated your public SSH key pair**.

Instructor Notes: Take a break here and check-in with your learners if there were any issues or difficulties.

Adding the SSH key to GitHub account

Step 1: Tell GitHub about your new public key. In the terminal, please hit ENTER after typing:

```
cat ~/.ssh/id_ed25519.pub
```

Important

Be careful: do not copy the content of your *private* key, but your **public** key. Your public key ends with .pub.

Speaker Notes: Now that you have generated your SSH key pair and confirmed it is there, it is time to tell GitHub about the new public key. This will allow you to securely connect to GitHub. To begin, we need to display the contents of your public key. This is the key that you will share with GitHub. In your terminal, type the following command: cat ~/.ssh/id_ed25519.pub Once you hit Enter, this command will print the contents of your public key to the terminal, which should end in .pub. The public key that you just generated

in the previous steps is what you will use to authenticate your machine with GitHub, and it is safe to share it.

Instructor Notes: Emphasize the importance of that learners only copy the content of the public key, which ends with .pub. They should **not copy their private key**. The private key should remain private at all times. Sharing the private key could compromise their security, so they should always double-check that they are looking at the correct key.

Adding the SSH key to GitHub account

Step 2: The output should be something like below. This is the output that needs to be copied in its **entirety**.

```
# The output looks like this. The characters after ssh-ed25519 will be different for you, however
ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAAIFEKiimOpcayfHhlbjmnIBAUX74FY/o20k9yFA16XOLm your_email@
```

! Important

Copy the contents of the output to your clipboard.

Speaker Notes: After printing your public key in the terminal, you need to copy the contents of the output to your clipboard.

Instructor Notes: Highlight that the characters after ssh-ed25519 will be different for each learner and the email will match the email the learners have added on an individual basis.

Adding the SSH key to GitHub account

Step 3:

- Login to github.com
- Navigate to your account settings by clicking on your profile photo (top right) and selecting **Settings**
- Click on **SSH and GPG keys** (left sidebar)
- Click on the green button **New SSH key** or **Add SSH key**.

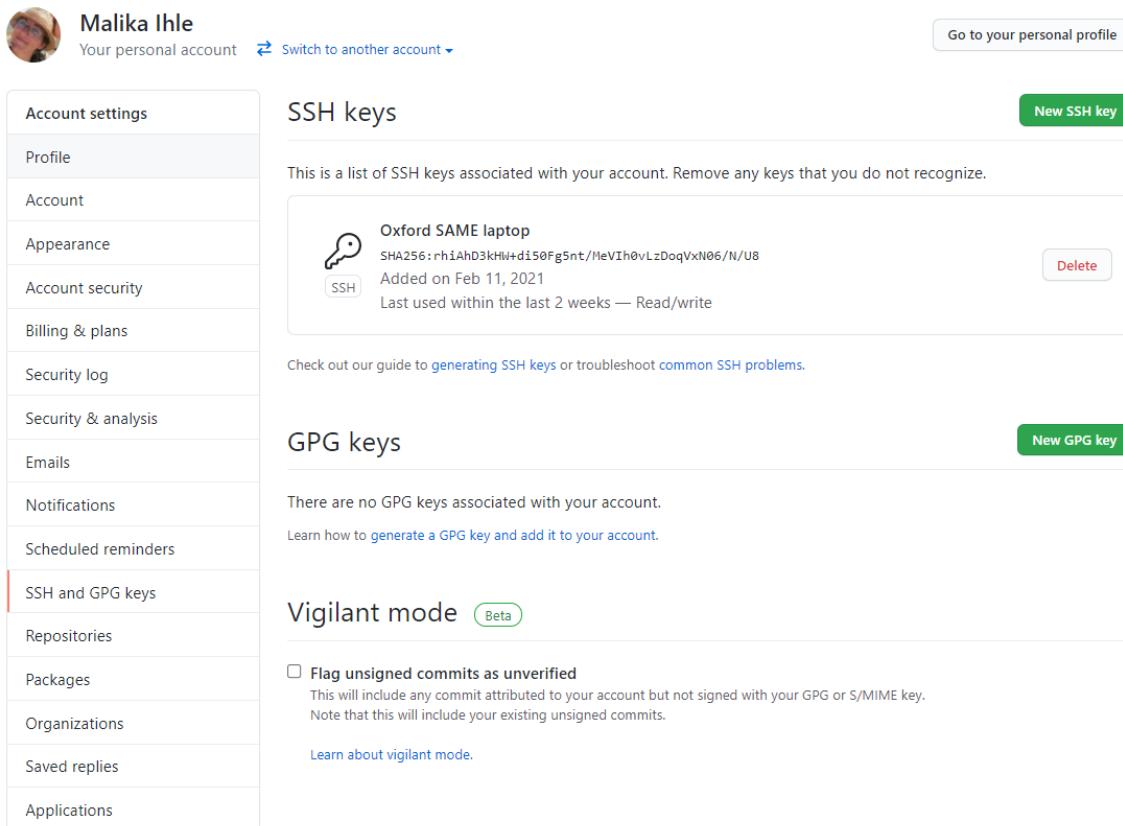

Speaker Notes: Now that you have your public key copied, it is time to add it to your GitHub account. This third step will enable you to authenticate your computer securely when interacting with GitHub. Here is how to do it:

- Log in to GitHub: Start by logging into your GitHub account at github.com.

- Go to your account settings: Once you're logged in, navigate to your account settings. To do this, click on your profile picture in the top right corner of the page. A dropdown menu will appear—select Settings.
- Access SSH and GPG keys: On the left-hand sidebar of the settings page, you'll see an option labeled SSH and GPG keys. Click on that to go to the section where you can manage your SSH keys.
- Add a new SSH key pair: In the SSH and GPG keys section, click the green button that says New SSH key or Add SSH key. This will open a form where you can paste your public key.

Instructor Notes: Switch to GitHub and give learners enough time to follow along. Highlight that they should compare the steps with the images in the following slides.

Adding the SSH key to GitHub account

The screenshot shows the GitHub Account Settings page for user Malika Ihle. The left sidebar lists various account management options, with 'SSH and GPG keys' highlighted. The main content area is titled 'SSH keys' and contains a list of existing keys. One key is shown: 'Oxford SAME laptop' (SHA256: rhiAhD3kHw+d150Fg5nt/MevIh0vLzDoqVxN06/N/U8), added on Feb 11, 2021, and last used within the last 2 weeks (Read/write). A 'Delete' button is visible next to the key entry. Below this, there's a note about generating SSH keys and troubleshooting common SSH problems. The 'GPG keys' section shows no keys associated with the account. The 'Vigilant mode' section is marked as Beta and includes an option to flag unsigned commits as unverified, with a note that this will include existing unsigned commits. A 'Learn about vigilant mode' link is provided.

Adding the SSH key to GitHub account

Step 4:

- In the **Title** field, add a descriptive label for the new key, e.g. something that would identify the device you just connected
 - For example, if you’re using a personal laptop, you might call this key “Personal MacBook Air”.
- Paste the contents of your clipboard into the **Key** text box
- Hit the green **Add key** button to save. Enter your GitHub password if prompted.

Speaker Notes: Now that you are on GitHub in the correct section to add a new SSH key, here is what you need to do next:

- Give a label to the key: In the “Title” field, add a descriptive label for the key. This helps you easily identify which device the key belongs to in the future. For example, if you’re adding a key for your personal laptop, you might label it “Personal MacBook Air” or something similar. This makes it clear which device the SSH key pair is associated with.
- Paste your public SSH key: Next, paste the contents of your clipboard (the public key you copied earlier) into the **Key** text box. Make sure the entire key is pasted in—starting from ssh-ed25519 and ending with your email address.
- Save the key: Once everything looks good, click the green **Add key** button to save the new key. If GitHub asks you to confirm your identity, enter your GitHub password to complete the process.

Instructor Notes: Go through these steps slowly and demonstrate where learners have to add the title and where they have to paste the SSH key pair they copied earlier. Remind them that if they are prompted for the password, they will **not see** the password when they are typing.

Adding the SSH key to GitHub account

Step 4: continued

SSH keys / Add new

Title

My Dell laptop

Key

```
ssh-ed25519 AAAAC3NzaC1IzDI1NTE5AAAAIFEKiimOpcayfHhlbjmnIBAUX74FY/o20k9yFA16XOLm  
your_email@email.com
```

Add SSH key

Adding the SSH key to *ssh-agent*

Managing your ssh keys is done via the [ssh-agent](#) software.

i Note

Depending on your system, the following might not be necessary. On most GNU/Linux distributions, your key will be automatically added to the ssh-agent after the first time you enter it. If you keep getting asked for your key each time you want to clone or push to a GitHub repository, you can follow the instructions on the next slides.

Speaker Notes: Now that you've added your SSH key to GitHub, the next step is to ensure that your SSH key is being managed securely on your local machine. This is where ssh-agent comes in. It is a software tool running in the background that handles your SSH keys, ensuring they are loaded and available when needed. By adding your key to ssh-agent, you ensure that the key is available for authentication without needing to re-enter the passphrase each time you interact with GitHub or other services that require SSH authentication.

Instructor Notes: Adapt the level of depth of your explanation as a function of the technical skills of your audience.

Adding the SSH key to ssh-agent

Step 1: In the command line, start the ssh-agent with this command:

```
eval "$(ssh-agent -s)"
```

This should give you this:

```
Agent pid 59566
```

Speaker Notes: Call up the ssh-agent and add this command. Compare your output to the output above. The command starts the ssh-agent in the background and sets up the necessary environment variables, allowing it to manage your SSH keys, ensuring they are available for authentication without requiring you to enter your passphrase each time you connect to a remote server or GitHub.

Instructor Notes: Follow along with your learners and check in regularly for issues.

Adding the SSH key to ssh-agent

Step 2: Add your SSH key to the ssh-agent by typing the entirety of this command:

```
ssh-add ~/.ssh/id_ed25519
```

Speaker Notes: Now that you called up the ssh-agent and it is running, the next step is to add your SSH key to it. This allows the agent to securely manage your key for authentication. In the terminal, type the following command: `ssh-add ~/.ssh/id_ed25519`. This command tells the ssh-agent to load your SSH key (`id_ed25519`) into memory, so it is ready to use when connecting to services like GitHub. After running this, the key will be available for SSH connections without you needing to re-enter your passphrase each time.

Instructor Notes: Check in regularly for any issues.

Testing the GitHub connection

Step 1: “Ask” GitHub at the command line if our connection is acceptable with the following code:

```
ssh -T git@github.com
```

Speaker Notes: Now that your SSH key is added to both GitHub and the ssh-agent, it is time to test if everything is working correctly. To do this, open your terminal and enter the following command: `ssh -T git@github.com`. This command sends a test SSH request to GitHub to check if your key is properly set up.

Instructor Notes: Leave enough time to complete this step and check in for any issues.

Testing the GitHub connection

Step 2: When asked about *fingerprinting*, type *yes*, then press ENTER to receive this output:

```
> Hi USERNAME! You've successfully authenticated, but GitHub does not
> provide shell access.
```

! This is it!

You have set up a new SSH key pair and successfully let GitHub know your identity to connect your computer to your GitHub account. These steps will only have to be repeated when you change computers. Let the fun begin!

Speaker Notes: After sending the test SSH request, you will potentially get asked about fingerprinting, to which you type yes and press ENTER. Then, if everything is configured correctly, GitHub will respond with a success message, like “Hi [your username]! You’ve successfully authenticated.”

Instructor Notes: If there is an issue, GitHub will let learners know so that troubleshooting can be done.

RECAP: Setting up Git

What have we done so far?

- Installed Git
- Configured Git
- Secured a connection between PC and GitHub via SSH key pair
- Added SSH key pair to GitHub account
- Tested the connection between your machine and GitHub

Ready!

Your Git and GitHub setup is now secure and ready to use!

Speaker Notes: Looking back, we have successfully completed the following steps:

- Installed Git: We have made sure Git is installed on your machine, so you can manage your repositories and interact with GitHub.
- Configured Git: We have set up your user name and email in Git, ensuring that commits are properly attributed to you.
- Secured a connection between your PC and GitHub via an SSH key pair: We generated a public SSH key pair and established a secure connection, allowing us to authenticate without needing a username and password each time.
- Added SSH key pair to your GitHub account: We uploaded the public SSH key to GitHub, enabling GitHub to recognize and trust your PC for secure access.
- Tested the connection: Finally, we ran a test to confirm that the SSH connection between your machine and GitHub works as expected.

With these steps complete, **your Git and GitHub setup is now secure and ready to use!**

Instructor Notes: Check in with your learners if they have followed along and if they know where they are at.

Pre-break survey

Brief check-in: **Your Turn!**

Figure 2: Select the prebreak survey option!

Speaker Notes: Before we head into the break, let us do a quick check-in to see where we are at. Scan this QR code and select the pre-break survey option. Answer a few questions to check your current understanding of version control and the topics we discussed in this first part of the class.

Instructor Notes: This pre-break survey serves to examine learners' current understanding of key concepts of the submodule. Guidance on interpreting the results:

- If more than 80% of the learners select the correct response option, show which one it is and move on.

- If less than 80% of answers are correct, let them discuss with each other for 1-2 minutes which one they selected, and why, and afterwards let them re-take the question. If they're above 80% correct the second time, move on, else show the correct response and explain why it is correct (plus maybe why the others are not).
- If more than 30% select a specific distractor answer, discuss it in class.

Accessibility Tip: This slide only works in a synchronous setting, skip if appropriate.

What is the main purpose of using Git in a project?

- To edit code directly on GitHub
- To automatically test and debug programs
- To track changes and collaborate on code with version control
- To back up files to the cloud without version history

Instructor Notes: C is the correct answer: Git is a version control system that helps you track changes, manage versions, and collaborate with others on the same project safely.

Why do we add an SSH key to our GitHub account when setting up Git?

- To store our Git username and password on the computer
- To allow our computer to connect securely to GitHub without entering a password each time
- To make Git automatically commit our changes
- To enable GitHub to edit our files directly on our computer

Instructor Notes: B is the correct answer: Adding an SSH key lets your computer authenticate with GitHub securely, so you can push and pull code without typing your password every time.

Break! 15 minutes

Instructor Notes: Adapt the break time as appropriate. If you are following the recommended lesson plan, the remaining slides are intended to be the homework assignment for your learners. Skip to overview slide (slide 96) and wrap up the lesson. Thoroughly explain the homework assignment and leave enough time for any questions.

Post-break survey discussion

What do we see in the results?

Speaker Notes: Let us have a look at these results.

Instructor Notes:

- **Aim:** Briefly examine the answers given to each question interactively with the group. Use visuals from the survey to highlight specific answers. Serves to clarify concepts and aspects that are not yet understood. Highlight specific answers given during the survey.

Accessibility Tip: Have people work in pairs if someone did not bring their phone/does not have a phone. This survey also cannot be completed in an asynchronous setting.

RStudio Project: What is it?

Local folder used to organize your work within a self-contained R storage.

- Contains all files related to project: R scripts, source files, location of the R working directory, RStudio workspace ...
- Includes shortcut to open the project directly in RStudio

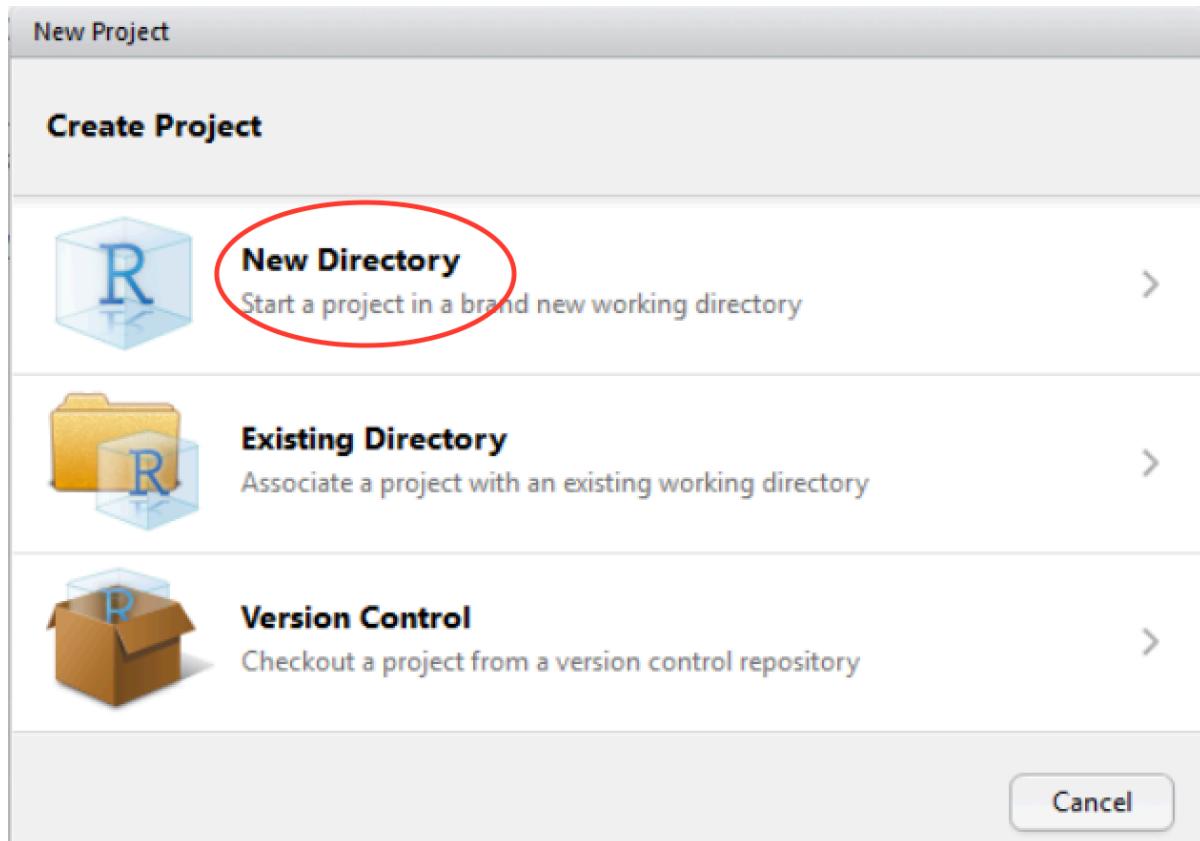

Speaker notes:

- RStudio Projects simplify working with multiple files
- A project is a folder on your computer that contains all files related to a specific analysis project and a shortcut that allows you to open the project directly in RStudio.

Instructor Notes: Open RStudio in the mean time and ask your learners to do the same.

Creating an RStudio Project

Step 1: Create a new project in RStudio as follows: File > New Project > New Directory

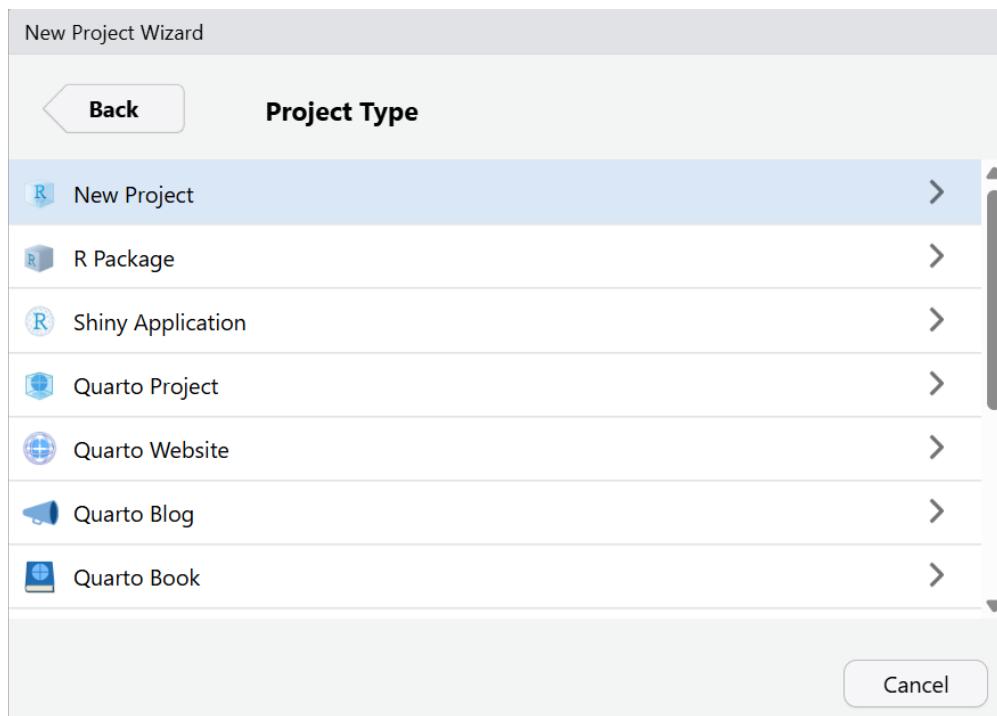

Speaker Notes: As a first step, we want to create a new project in RStudio as follows:
File > New Project > New Directory.

Instructor Notes: Demonstrate in your own RStudio how to generate a new project.

Creating an RStudio Project

Step 2: In the New Project Wizard screen, click on New project:

Speaker Notes: As a second step, in the New Project Wizard screen, click on New project.

Creating an RStudio Project

Step 3: Give your project a name (e.g.'my_first_test_repo') and ensure that **Create a git repository** is ticked. Next, click on **Create Project**.

Back

Create New Project

Directory name:

my_first_test_repo

Create project as subdirectory of:

C:/Users/Malika.Ihle/Desktop

Browse...

Create a git repository

Use renv with this project

Open in new session

Create Project

Cancel

i Note

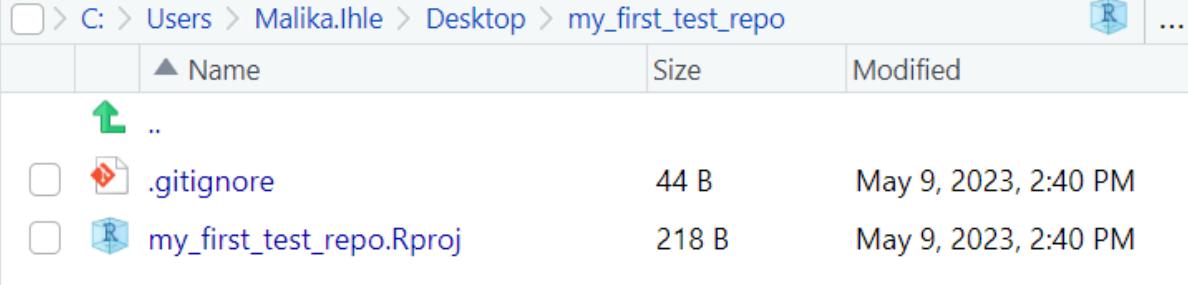

RStudio will create a new folder containing an empty project and set it as the new R working directory.

Speaker Notes: Give your project a name (e.g.'my_first_test_repo') and ensure that *Create a git repository* is ticked. Next, click on **Create Project**.

Creating an RStudio Project: Important files

Two files are created in the otherwise empty project:

- **.gitignore**: Specifies files that should be ignored by the version control system (e.g. sensible data files that should not be made public, or documentation that you don't need version controlled).
- **my_first_test_repo.Rproj**: Configuration information for the RStudio project.

A screenshot of a Windows File Explorer window. The path is C:\Users\Malika.Ihle\Desktop\my_first_test_repo. The folder contains two items: a file named '.gitignore' and another file named 'my_first_test_repo.Rproj'. The '.gitignore' file is 44 B and was modified on May 9, 2023, at 2:40 PM. The 'my_first_test_repo.Rproj' file is 218 B and was also modified on May 9, 2023, at 2:40 PM. The RStudio logo icon is visible in the top right corner of the window.

	Name	Size	Modified
	..		
	.gitignore	44 B	May 9, 2023, 2:40 PM
	my_first_test_repo.Rproj	218 B	May 9, 2023, 2:40 PM

Speaker Notes: When you create a new project, two important files are automatically created. The first is the `.gitignore` file, which tells Git to ignore certain files, such as sensitive data or documents that do not need to be tracked by version control. This helps keep your project clean and secure. The second file is `my_first_test_repo.Rproj` (depending on how you named your project file), which contains configuration information for your RStudio project. This file helps RStudio remember your project settings and keeps everything organized, making it easier to work on your project.

Setting up a small practice project

We will now generate a small project to practice version control on.

Step 1: Download dataset to practice analyses on.

Download dataset (.csv)

Speaker Notes: We are now going to create a small project to practice using version control. The first thing we will do is download a dataset that we can use for practicing analysis. This will give us something to work with as we learn how to track changes and manage versions of our project using Git.

Instructor Notes: Make the practise dataset available for participants. Use download button on slides or provide dataset separately.

Setting up a small practice project

Step 2: Create a new R script File > New File > R script and save it as *myscript.R*. Then add the code below to your R script.

```
mydata = read.csv("example_data.csv")
plot(mydata$xdata, mydata$ydata)
```

Speaker Notes: Next, create a new R script by going to File -> New File -> R script in RStudio. Once the script is open, save it as *myscript.R*. After saving the file, add the code provided to your R script. This will be the starting point for your practice project.

Instructor Notes: Emphasize that the code needs to be copied as is, and that your audience needs to pay attention to spelling and that the file name of the practise data matches the code.

Setting up a small practice project

Step 3: Run the code and check your directory. It should now contain four files:

	Name	Size	Modified
	..		
<input type="checkbox"/>	.gitignore	44 B	May 9, 2023, 2:40 PM
<input type="checkbox"/>	my_first_test_repo.Rproj	218 B	May 9, 2023, 2:40 PM
<input type="checkbox"/>	example_data.csv	144 B	May 9, 2023, 2:48 PM
<input type="checkbox"/>	myscript.R	70 B	May 9, 2023, 2:48 PM

Speaker Notes: Run the code and check your directory in the bottom right panel. It should now contain four files: the *.gitignore* file, the RStudio Project file, the example data *.csv* file and your R script.

Instructor Notes: Run the code by pressing Ctrl + Enter on a Windows PC, and Command + Enter on a MacOS.

Getting your project under version control

Step 1: Find the git version control pane in the top right corner of RStudio in the **Git** tab.

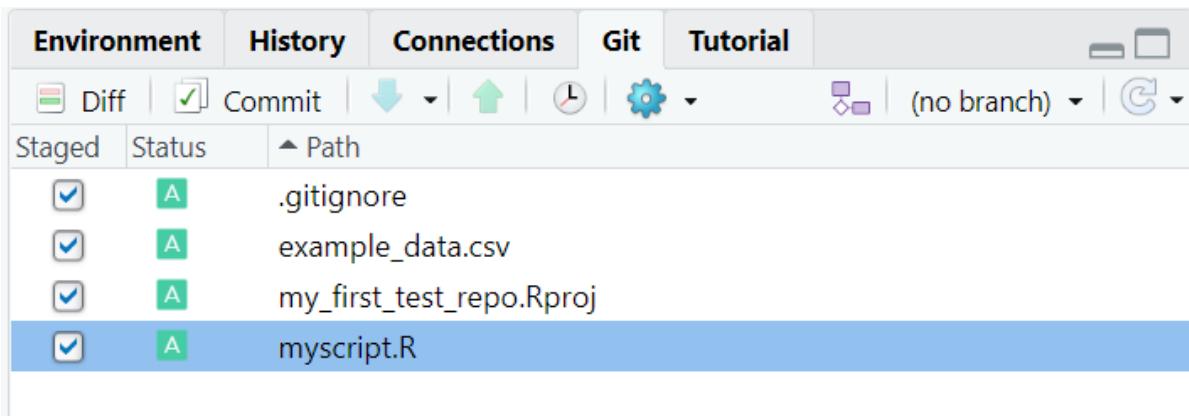

Speaker Notes: AFind the git version control pane in the top right corner of RStudio in the **Git** tab and click on it.

Instructor Notes: If the Git tab does not appear, try one of the following options:

- In order to see the Git tab in the upper right pane in RStudio, one must create an RStudio project, as follows. Starting from the RStudio main panel, there is **no git tab** prior to loading a project.
- Click *View->Panes->Zoom Git*, to make it appear.
- Check your Git installation.

Getting your project under version control

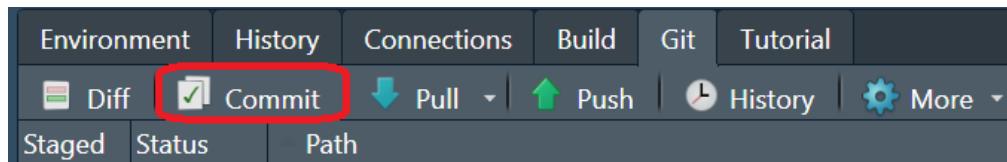

Step 2: Hover the mouse pointer over the yellow ? marks in GitHub, you'll see a tooltip telling us that the file is **untracked**. This means that git is not tracking versions of this file. Tick **staged** for each file.

Speaker Notes: We now what to perform what is called *staging* our files. Staging is like preparing your changes before saving them. When you make changes to a file (like adding new code), Git doesn't automatically track those changes. To tell Git which changes you want to save, you "stage" them. In RStudio, you can do this by selecting the changes you want to keep and clicking "Stage" in the Git tab. In this step, hover the mouse pointer over the yellow ? marks in GitHub, you'll see a tooltip telling us that the file is **untracked**. This means that git is not tracking versions of this file. Tick **staged** for each file.

Getting your project under version control

Step 3: Our staged files are now ready for the first **commit**. Click on the `commit` button.

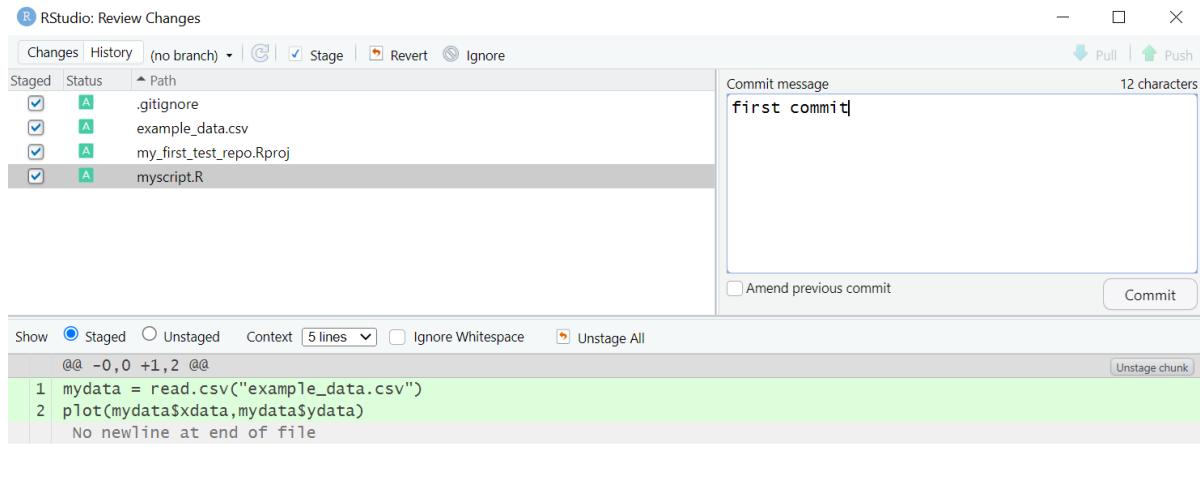

Speaker Notes: In a next step, we want to *commit* our changes. Committing is when you actually save the changes to your Git history. After staging your changes, you create a "commit," which is like taking a snapshot of your project at that moment. When you commit, you also write a short message describing what changes you made (e.g., "added new analysis to script"). This helps you keep track of what's been done over time and allows you to go back to previous versions if needed. Taken together, staging is selecting the changes you want to keep, and committing is actually saving those changes with a description for future reference.

Instructor Notes: Check if staging and committing have been understood as concepts before continuing.

Getting your project under version control

Step 4: Specify a **commit message**, which is a brief description of the changes you made. For now, we will add the commit message *First commit*. Then click on **Commit**.

Speaker Notes: You want to specify what changes exactly you have made. This can be done via a *commit message*. Writing a good commit message is essential for keeping track of the changes you make to your project. Clear and concise commit messages help you and others understand the purpose of each change, making it easier to review or roll back changes later.

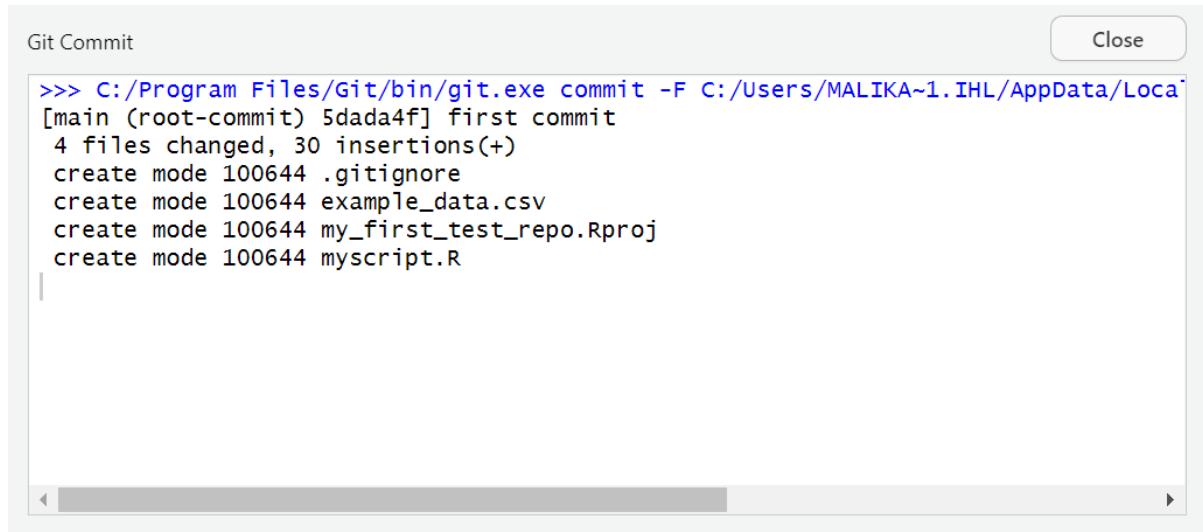

Instructor Notes: Here are some tips for writing helpful commit messages:

- Be clear and specific: A commit message should clearly describe what changes you've made. Instead of something vague like "updated script," be specific—like "added data cleaning steps to the script" or "fixed typo in analysis code."
- Use the imperative mood: Commit messages are usually written in the imperative mood, as if giving a command. For example, instead of "I added a new function," say "Add function to calculate summary statistics." This keeps messages consistent and to the point.
- Keep it brief: Your commit message does not need to be long. Aim for a short, clear description. If the change requires more explanation, you can provide additional details in the commit body (though a short, effective title is usually enough).

- Describe the Why, not just the What: If you are fixing a bug or adding a feature, include why you made the change. For example, “Fix issue where NA values caused the analysis to fail” is more useful than just “Fix bug.”
-

Getting your project under version control

Step 5: Check the message from git and then click on close - finished!

The screenshot shows a 'Git Commit' dialog box. At the top left is the title 'Git Commit'. At the top right is a 'Close' button. The main area contains a terminal-like output of a git commit command:

```
>>> C:/Program Files/Git/bin/git.exe commit -F C:/Users/MALIKA~1.IHL/AppData/Local/Temp/MyFirstTestRepo/commitmsg.txt  
[main (root-commit) 5dada4f] first commit  
 4 files changed, 30 insertions(+)  
  create mode 100644 .gitignore  
  create mode 100644 example_data.csv  
  create mode 100644 my_first_test_repo.Rproj  
  create mode 100644 myscript.R
```

Below the terminal output is a scroll bar.

Making changes

Now we want to make some actual changes to practise using Git and to show how Git handles modifications of files.

Step 1: Add the following code to your existing R script:

```
# some guesses for the parameters.  
p1 = 1  
p2 = 0.2  
  
# do the fit  
fit = nls(ydata ~ p1*cos(p2*xdata) + p2*sin(p1*xdata), data = mydata, start = list(p1=p1,p2=p2))
```

```
#Plot the fitted line  
new = data.frame(xdata = seq(min(mydata$xdata),max(mydata$xdata),len=200))  
lines(new$xdata,predict(fit,newdata=new))
```

Speaker Notes: Now that we have set up our RStudio project, it is time to make some actual changes to practice using Git and see how it handles modifications in files. First, open your existing R script (e.g., myscript.R), and add the code to it.

Instructor Notes: Copy- Paste the code from the slides or pay attention that the code is identical if typed by hand.

Making changes

Step 2: Change the command that plots our data in this file.

Change the line

```
plot(mydata$xdata,mydata$ydata)
```

to

```
plot(mydata$xdata,mydata$ydata,col='red')
```

and run this code.

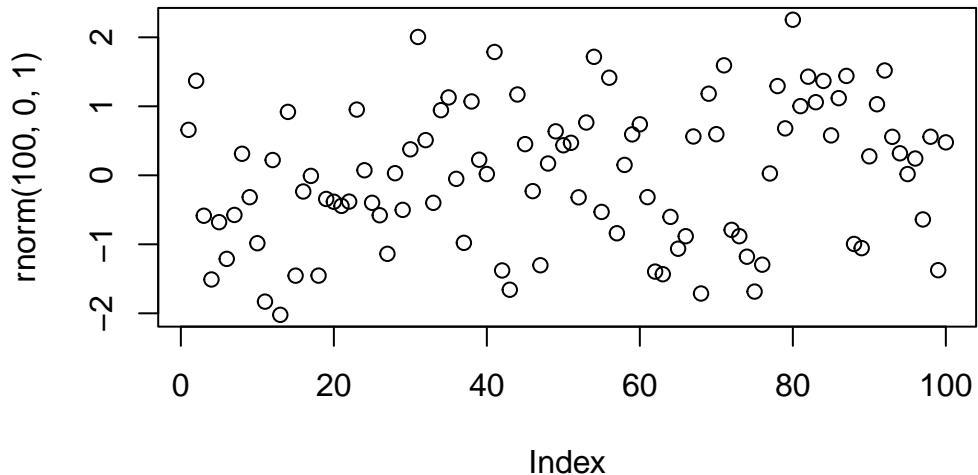

Speaker Notes: Change the command that plots our data in this file. Specifically, change the line `plot(mydata$xdata, mydata$ydata)` to `plot(mydata$xdata, mydata$ydata, col='red')` and run this code by pressing Ctrl + Enter.

Instructor Notes: Remind learners to run their code at the end.

Making changes: Optional Exercise

Step 3(optional): Create another R file with `File > New File > R script`. Save as `simulation_script.R`. Then add and run the code below in the new R script:

```
#Simulate some data  
plot(rnorm(100,0,1))
```

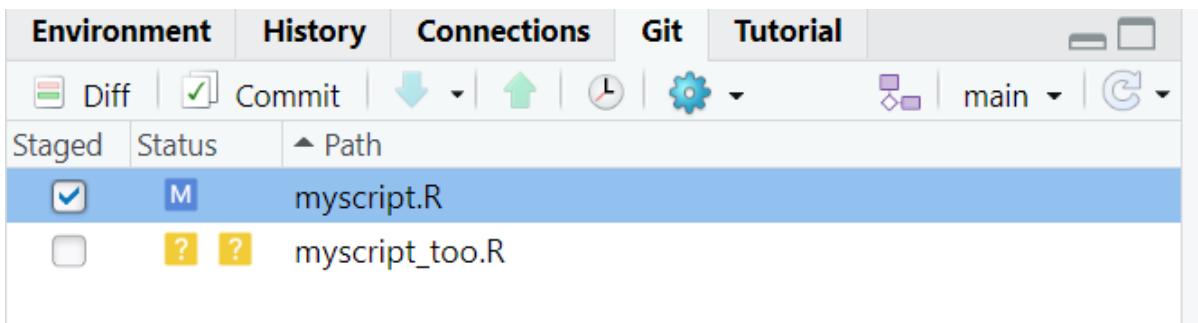

Instructor Notes: Optional exercise for more advanced learners if they finished before the others.

Committing changes

Click on the `git` tab in the top right corner. Two files appeared, the script we modified and the new script.

Step 1: Click on the `staged` box to stage changes for the *first* script.

Speaker Notes: Now that you have clicked on the Git tab in the top right corner of RStudio, you should see two files listed: the script you just modified (e.g., myscript.R) and any new scripts that were added if you completed the optional exercise. For the script you modified first, click on the staged box next to it. This marks your changes as ready for the next step, which is committing the changes to your Git history. Do not stage the second script for now. Once you have staged your changes, you're all set to commit them and save a snapshot of your progress.

Instructor Notes: Ask a learner to explain the concept of staging to check for comprehension of the concept behind it.

Committing changes

Step 2: Click on Diff for a reminder summary of what changed. Then add a commit message and click commit.

```

@@ -1,2 +1,13 @@
1 mydata = read.csv("example_data.csv")
2 plot(mydata$xdata,mydata$ydata)
No newline at end of file
2 plot(mydata$xdata,mydata$ydata,col='red')
3
4 # some guesses for the parameters.
5 p1 = 1
6 p2 = 0.2
7
8 # do the fit
9 fit = nls(ydata ~ p1*cos(p2*xdata) + p2*sin(p1*xdata), data = mydata, start = list(p1=p1,p2=p2))
10
11 #Plot the fitted line
12 new = data.frame(xdata = seq(min(mydata$xdata),max(mydata$xdata),len=200))
13 lines(new$xdata,predict(fit,newdata=new))

```

! Important

Remember that Git track *differences* between two files. Lines that have been added are green. Lines that have been removed are red.

Speaker Notes: Now that your changes are staged, it is time to commit them. First, click on Diff to view a summary of what exactly has changed in your script. This gives you a quick reminder of the edits you made. Once you have reviewed the changes, add a brief and concise commit message that describes what you have done, like “Add plot to visualise XX”. Finally, click commit to save these changes to your Git history. With that, your changes are now securely recorded in your Git project!

Instructor Notes: Leave enough time for learners to review the Diff tab and the changes they made. This is a critical step in the process of understanding version control in RStudio.

Practical exercise 1

- If you have not already done so, create a second R script and save it in your RStudio project folder.
- Stage the second script and write a new commit message.

- In the git tab, press the **History** button to review the change and commit history of your files.

i Note

By default, the history search feature will show all files added, changed, or deleted for each commit. This can be extremely useful for finding bugs or looking back to how your project looked a few months ago. However, it is often more practical to review the changes made to a single file over time; this enables, for example, clear tracking of the evolution of data cleaning and analysis steps in your project.

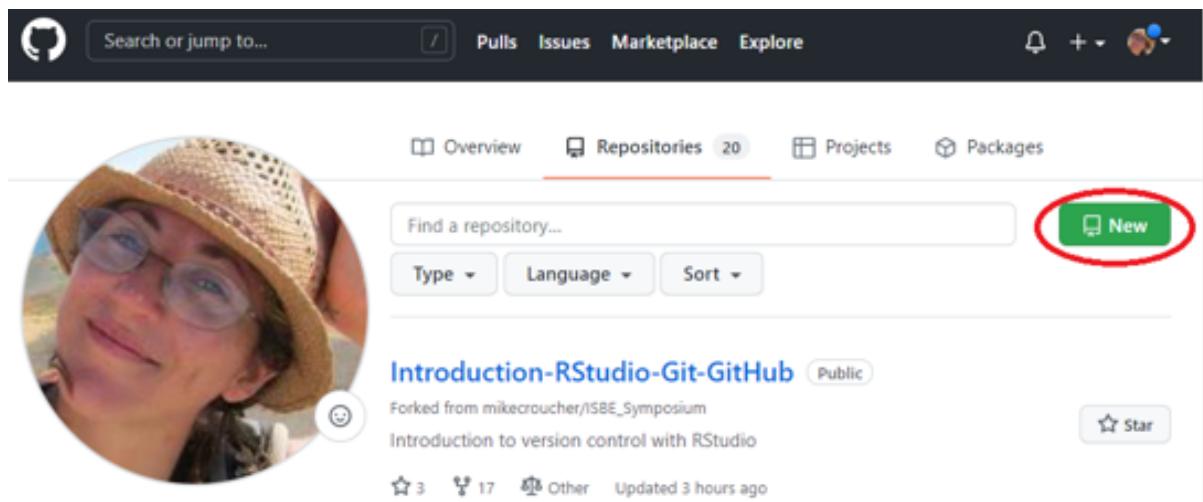

Speaker Notes: If you have not already done so, create a second R script and save it in your RStudio project folder. Stage the second script and write a new commit message. In the git tab, press the **History** button to review the change and commit history of your files.

Instructor Notes: Ensure that learners save the second script in the same RStudio project folder as the first script.

Connecting the local repository to GitHub

The project is now under version control. Time to create a **new GitHub repository** and **upload** to GitHub!

Step 1: Log into GitHub and go to your profile page. On the **repositories** tab, click **New**.

Speaker Notes: Now that your project is under version control in RStudio, the next step is to connect it to your GitHub account so that you can upload your project and access it online. First, log into your GitHub account and go to your profile page. Once you are there, click on the **Repositories** tab. From this page, click the **New** button to create a new GitHub repository. Creating this new repository on GitHub will allow you to upload your local project to GitHub, making it accessible from anywhere and easier to share or collaborate on. After the repository is created, you can connect it to your local RStudio project in the next steps.

Instructor Notes: Learners should be logged into their GitHub accounts at this point.

Connecting the local repository to GitHub

Step 2: Give the repository a name and click **Create Repository**.

Create a new repository
A repository contains all project files, including the revision history. Already have a project repository elsewhere? [Import a repository](#)

Required fields are marked with an asterisk (*).

Repository template

Start your repository with a template repository's contents.

Owner * /

Great repository names are short and memorable. Need inspiration? [How about crispy-guide?](#)

Description (optional)

Public Anyone on the internet can see this repository. You choose who can commit.

Private You choose who can see and commit to this repository.

Initialize this repository with:

Add a README file This is where you can write a long description for your project. [Learn more about READMEs](#)

Add .gitignore

Choose which files not to track from a list of templates. [Learn more about ignore files](#)

Choose a license

A license tells others what they can and can't do with your code. [Learn more about licenses](#)

You are creating a public repository in your personal account.

Create repository

Speaker Notes: Give the repository a name and click **Create Repository**.

Connecting the local repository to GitHub

Step 3: Configure the repository in the **Quick Setup** screen. Select the **SSH** tab and make sure the url shown in the blue box should start with git@github.com.

Speaker Notes: After creating the new repository, you will be directed to the **Quick Setup** screen. Here, you need to configure the repository for SSH access. Select the **SSH** tab, and

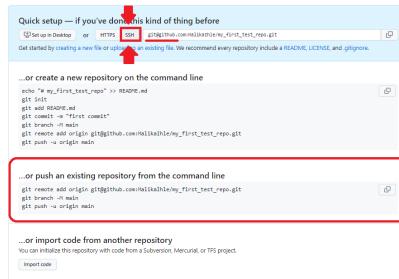

make sure the URL shown in the blue box starts with git@github.com. This ensures that your project will be connected securely to GitHub using SSH, allowing you to push and pull changes without needing to enter your username and password every time. Once you have confirmed this, you are ready to link your local repository to the new GitHub repository.

Instructor Notes: In version control, pushing and pulling refer to how you sync your local project with a remote repository, like GitHub.

- **Pushing** means uploading your changes from your local project to the remote repository. When you push, you are sending your latest commits (the saved changes) to GitHub, making them available for others or for backup.
- **Pulling** means downloading the latest changes from the remote repository to your local project. If someone else has made changes to the project or you've worked on it from another computer, pulling updates your local version with those new changes.
- In short, pushing uploads your work, and pulling brings in updates from others.

Connecting the local repository to GitHub

Step 4: Copy the commands from the **or push an existing repository from the command line** to your clipboard with the GitHub copy button.

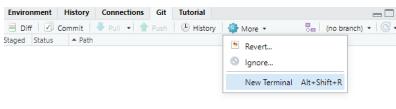

Speaker Notes: After selecting the SSH tab and confirming the URL, you'll see a section titled **or push an existing repository from the command line**. This section provides the commands you need to connect your local project to the newly created GitHub repository. Click the **copybutton** next to the commands to copy them to your clipboard. These commands will be used in your terminal to link your local repository to GitHub and push your changes.

Once you have copied the commands, you can paste them into your terminal to complete the connection between your local project and the GitHub repository.

Instructor Notes: Make sure that learners are clear the email address will be tailored to each individual user.

Connecting the local repository to GitHub

Step 5: Go to RStudio, navigate to the git tab and Click on More > New Terminal.

Speaker Notes: Now, go to RStudio. In the Git tab, click on More > New Terminal. This will open a new terminal window within RStudio, where you can paste the commands you copied from GitHub.

Instructor Notes: Help learners paste the commands pasted from GitHub.

Connecting the local repository to GitHub

Step 6: Paste the git commands from your clipboard into the terminal and press enter to execute them. Insert your SSH key password if prompted or type

yes

when a sentence about continuing appears in the terminal.

```
C:\Users\Nalika.Dhile\Desktop\my_first_test_repo>git remote add origin git@github.com:NalikaDhile  
my_first_test_repo.git  
C:\Users\Nalika.Dhile\Desktop\my_first_test_repo>git branch -M main  
C:\Users\Nalika.Dhile\Desktop\my_first_test_repo>git push -u origin main  
Enter passphrase for key '/c/Users/Nalika.Dhile/.ssh/id_ed25519':
```

Speaker Notes: The terminal is where you will paste and then run the Git commands to link your local repository to GitHub and push your changes. Paste the git commands from your clipboard into the terminal and press enter to execute them. Insert your SSH key password if prompted or type yes when a sentence about continuing appears.

Connecting the local repository to GitHub

Step 7: Check that your local repository with your RStudio Project appears on your GitHub profile (please refresh the page once).

Note

You only need to upload your local repository **once** to GitHub. In the subsequent section, we explain how to sync (or **push**) your local changes in your RStudio project with the remote repository you just created on GitHub.

Speaker Notes: Check that your local repository with your RStudio Project appears on your GitHub profile. For this, you will need to refresh the GitHub page. Important: You only need to upload your local repository **once** to GitHub. In the subsequent section, we explain how to sync (or **push**) your local changes in your RStudio project with the remote repository you just created on GitHub.

Instructor Notes: Ensure that learners do not leave out the refreshing of the GitHub page. Check that your learners have followed the steps so far and check in with them about any issues.

Making changes: Adding a README to your RStudio Project

Imagine that as a follow-up step, we want to add a README file to the RStudio project folder.

Note

A README file is a short document that explains what your R project is about and can be viewed as a sort of *Welcome Guide*. It usually includes things like:

- What the project does and who made it
 - What files or data are included
 - How to use or run the code
 - Any special setup or packages needed
-

Adding a README to your RStudio Project

Step 1: In RStudio, click on **File > New File > Text File**. Add the following text to the file and save it as **README.md**:

```
# My Example Repo
```

```
This repo is used to demonstrate GitHub to users of R and R Studio.
```

Speaker Notes: As a next step, we want to add a README file. In RStudio, go to *File > New File > Text File*. This will open a blank text file. Next, add the given text to the file and save the file as README (in capital letters by default).

Instructor Notes: Highlight that learners need to **save** the file.

Adding a README to your RStudio Project

Step 2: In the **git** tab, you should see the new **Readme.md** file (and only that one!). Stage the file and press **commit**.

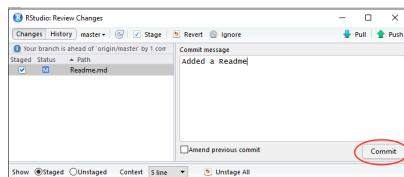

Speaker Notes: In the **git** tab, you should see the new **Readme.md** file (and only that one!). Stage the file and press **commit**.

Instructor Notes: Encourages your learners to revise the process of staging and committing again.

Adding a README to your RStudio Project

Step 3: Add a new commit message and press **Commit** in the bottom right corner.

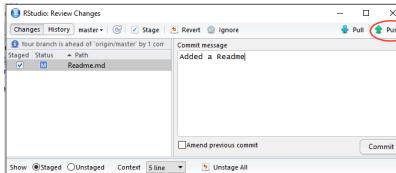

Speaker Notes: Add a new commit message and press **Commit** in the bottom right corner.

Instructor Notes: Regularly check for questions or issues.

Adding a README to your RStudio Project

Step 4: Push the changes to upload to GitHub by pressing the button in the top right corner with the green arrow pointing upwards.

Speaker Notes: Push the changes to upload to GitHub by pressing the button in the top right corner with the green arrow pointing upwards.

Instructor Notes: Demonstrate the location of the green upward arrow in RStudio.

When to stage and commit?

! Important

Great question! The point of version control is to have a **track record** of changes and that you can undo/redo any changes at any time. Therefore, you should stage and commit your changes to version control whenever you finished a clear, logical “unit”, e.g.:

- Added a code chunk or function
 - Cleaned your dataset
 - Created a new figure
 - Updated a paragraph
-

RECAP: Version control in RStudio with Git

What have we done so far?

- Created an RStudio Project in a local repository
- Created files for the project (code, downloaded data etc.)
- Added version control to our project in the local repository
- Made changes and commit these changes locally

- Connected the local repository with a remote repository
- Synchronised (= *pushed*) the local changes to the remote repository

Speaker Notes: Congratulations! We have successfully completed the following steps to set up and manage our project with Git:

- First, we created an RStudio Project in a local repository, where we'll store all the files related to our project.
- Then, we added the necessary files for the project, such as the R script and any downloaded data.
- After that, we enabled version control for our project by adding Git to the local repository, allowing us to track changes.
- We made some changes to our files and committed those changes locally, saving snapshots of our progress.
- Next, we connected our local repository to a remote GitHub repository, making it possible to store and share the project online.
- Finally, we synchronized our local changes with the remote repository by pushing them to GitHub, ensuring our work is safely stored and accessible.

With these steps, we have set up a complete version control workflow for our project, both locally and on GitHub.

Instructor Notes: Check in with your learners about questions.

OVERVIEW: The Git/GitHub workflow

! What do I need to do?

1. Make changes locally
2. Stage changes locally
3. Commit changes locally with a commit message
4. Push local changes to the remote repository on GitHub

Once you have brought your local repository under version control and connected the remote repository, you will find yourself **repeating the same steps above over and over**.

Speaker Notes: Once your local repository is under version control and connected to a remote repository on GitHub, you will follow a repeated workflow to keep everything updated. By following this workflow, you ensure that your project remains organized, and all changes are properly tracked both locally and on GitHub. Here is the process:

- **Make changes locally:** Start by editing your files, whether it is updating code, adding new content, or modifying existing data.
 - **Stage changes locally:** After making changes, you'll select which changes you want to keep by staging them. This prepares them for committing.
 - **Commit changes locally** with a commit message: Once your changes are staged, you commit them with a message that explains what was changed. This helps keep track of your project's history.
 - **Push local changes to the remote repository** on GitHub: Finally, after committing, you push your changes to GitHub, syncing your local work with the remote repository and making it available online.
-

Activity: One-Minute Paper!

Why is version control important and useful? *Take one minute to write down your thoughts on some paper.*

Speaker Notes: To conclude this class, a question for you: Why is version control important and useful? Think for yourselves for a few moments, then write down your thoughts. You have one minute for this.

Instructor Notes: Use the one-minute paper activity for this task. You will get immediate insight into whether learners understood the broad lines of the usefulness of Git and GitHub.

Why is version control important and useful?

Some thoughts ...

- **Tracks** every change in your R project and acts as a “time machine” for your code/files
- **Makes mistakes easy to fix** because you can revert to earlier versions anytime
- **Improves reproducibility** by seeing *what* changed, *when*, and *why* it changed
- **Provides a backup via GitHub** for easy sharing and access anywhere

Speaker Notes: Using Git with your R project offers several key benefits:

- Tracks every change: Git keeps a record of every modification you make to your project, acting like a “time machine” for your code and files. This allows you to see how your project evolves over time.

- Makes mistakes easy to fix: If something goes wrong, you can easily revert to an earlier version of your project, making mistakes much easier to fix without losing progress.
- Improves reproducibility: With Git, you can track what changes were made, when they were made, and why. This helps you maintain a clear record of your work, which is especially useful for reproducing results or sharing your process with others.
- Provides a backup via GitHub: By pushing your project to GitHub, you create a secure backup of your work. Plus, you can easily share your project and access it from anywhere.
- **In short, Git not only helps manage changes and mistakes but also enhances the reproducibility and accessibility of your work.**

Instructor Notes: - **Aim:** To work out the relevance of the topic to your learners. - In an interactive setting, discuss how the new skills could be applied in practice with specific examples. - Examine downfalls and practical obstacles.

Reflection

Take 10 minutes now to reflect upon where in your **own current or future research** you could use Git. Write then the steps you will need to implement what you have learned here in that project and which barriers you may face” (e.g., technical, project partners/supervisors, etc.)

Speaker Notes: Let’s do a brief reflection question to conclude this session. Take 10 minutes now to reflect upon where in your **own current or future research** you could use Git. Write then the steps you will need to implement what you have learned here in that project and which barriers you may face” (e.g., technical, project partners/supervisors, etc.).

Instructor Notes: By this point, we touched upon long term sustainability, and this reflection task may help a bit preparing for that. This task gets learners thinking about applying it to their own research projects, even if they are only hypothetical at this point.

Assignment: Practising the workflow

- In a new local folder, create a new RStudio Project named **git_practice**.
- Download the practise_data.csv file and save it in your project folder

Download dataset for the assignment

This is a dataset containing the number of athletes that participated in the Summer Olympics over the years.

💡 Tip

When creating the new RStudio project, make sure to check **Create a git repository**.

Speaker Notes: To consolidate what we have discussed and explored today, here is the homework assignment. In a new local folder, create a new RStudio Project named **git_practice**. Download the practise_data.csv file and save it in your project folder. This is a dataset containing the number of athletes that participated in the Summer Olympics over the years. Next, create a new R script and write code to read in data, inspect the data and plot the number of athletes over time. Stage and commit changes. Create a new repository on GitHub and connect it with your new local repository. Push your changes to GitHub and check your work.

Instructor Notes:

- **Aim:** Explain the homework assignment and the rationale behind the homework. Provide the dataset as separate file or via slides.
 - Examine whether/how it will be assessed
 - Mention scoring rubrics, if applicable
 - Design a peer-review system for assignments to place learners in the role of reviewer and author
-

Assignment: Practising the workflow

(cont.)

- Create a new R script and write code to read in data, inspect the data and plot the number of athletes over time
- Stage and commit changes
- Create a new repository on GitHub and connect it with your new local repository
- Push your changes to GitHub

💡 Tip

For the plot, use `geom_line()` to plot the number of athletes at the Summer Olympics over the years.

Instructor Notes: Learners should demonstrate:

- A working Git-enabled RStudio project

- A clear commit history showing each logical step
- The final project pushed to GitHub (if possible)
- Example code: `ggplot(athletes, aes(x = Year, y = Athletes)) + geom_line(color = "blue", size = 1) + geom_point(color = "red", size = 2) + labs(title = "Number of Athletes in the Summer Olympics", x = "Year", y = "Athletes") + theme_minimal()`

Example code:

```
data <- read.csv("data.csv")
head(data)
summary(data)
plot(data$xdata, data$ydata,
      main = "Simple Scatterplot",
      xlab = "xdata",
      ylab = "ydata")
```

Take-home message

What are you taking away from today?

 Keep practising!

It is all about practise until you develop a routine.

Speaker Notes: Let's collect as a group. What are you taking away from today?

Instructor Notes:

- **Aim:** End lesson on clear take-home message that are interactively compiled by learners.
-

To conclude: Survey time!

Figure 3: Select the finishing survey option!

Speaker Notes: Before we end for today, let us do a quick check-in to see where we are at now at the end of class. Scan this QR code and select the finishing survey option. Answer a few questions to check your current understanding of version control and the topics we discussed today.

Instructor Notes:

- **Aim:** This post-submodule survey serves to examine learners' current knowledge about the submodule's topic.
- Use identical questions as in the pre-submodule survey to be able to directly compare
- Exchange the QR-code to match your own survey and test beforehand.

Accessibility Tip: This slide is only applicable to a synchronous classroom setting. Skip if not applicable.

Which of the following concepts or skills do you now feel more confident about in relation to version control? (Select all that apply)

- a. Git
 - b. GitHub
 - c. Repositories
 - d. RStudio Project
 - e. I am (still) not sure about any of these concepts.
-

**On a scale of 1 to 5, how comfortable are you with using Git for version control?
(1 = Not comfortable at all, 5 = Very comfortable)**

- a. 1
 - b. 2
 - c. 3
 - d. 4
 - e. 5
-

Discussion of survey results

What do we see in the results and how do they compare to the previous ratings?

Speaker Notes: Discussion of the survey results, particularly the second question for comparison.

Instructor Notes:

- **Aim”:** Briefly examine the answers given to each question interactively with the group.
 - Use visuals from the survey to highlight specific answers.
-

Help and support

If you get stuck, there is plenty of help available:

- [Using Git with RStudio](#) for an introductory overview
- [Git Guides on staging and committing](#) for an overview of the workflow
- [Git and GitHub learning resources](#) for free interactive courses built in GitHub
- [Git Cheatsheet](#) featuring tips on installation, setup, staging, committing and pushing
- [The LMU OSC RStudio/Git tutorial](#) for similar exercises and advanced materials

Speaker Notes: There is always help out there! Here are some resources where you can get and find help.

Instructor Notes: Highlight particularly relevant resources for your learners.

Thanks!

Ready for the next session?
